

Panel Install & Reseller API Activation Check

Xtream-Masters panel — Mr7tv account · Guide for the server owner · Commands ready to copy & paste

This guide covers two linked issues: the **panel install domain** after the domain change (the root cause), and **activating the Reseller API** and verifying it from both the panel and the server.

Key values

Item	Value
Our server (must be whitelisted in the panel)	158.220.81.202
Existing access codes (Reseller API)	msAPIufgk · resellerapi
Endpoint format (per docs)	http://{server-dns}:{stream-port}/{code}/reseller/index.php
Old domain stuck in the API	mr7-4k.live — ⚠️ does not resolve (old install domain)
Current panel domain (admin)	mr7-4k.sbs:2052 (behind Cloudflare)
Origin IP	205.237.107.54
API docs	https://ottpanel.tv/xm_reseller_api_doc.html

To fill in: {KEY} = api_key from API Settings, {PORT} = stream port, {PKG} = a package id for testing, {NEW} = the final approved domain.

Section A — Panel install domain (root cause)

The panel was installed on one domain, then changed. The old domain mr7-4k.live is still stored in the stream/API settings, so access-code links are built on a domain that does not resolve. Unify all references on the final domain {NEW} (most likely mr7-4k.sbs):

- DNS:** add an **A** record for every hostname used (admin + stream + API) in the {NEW} zone ← 205.237.107.54 . On Cloudflare, set the **stream-port records to DNS only (grey cloud)**, since Cloudflare only proxies specific HTTP ports (80, 8080, 2052, 2082, 2086, 2095...).
- Panel General Settings:** update the **Panel URL / Access URL / Stream DNS** field (used to build access-code and stream links) from mr7-4k.live to {NEW} .

3. **Servers / Load Balancers:** for each server, update the **Server Domain / DNS** field to `{NEW}`.
4. **nginx:** add `{NEW}` to `server_name` on the admin and stream ports, with a valid SSL certificate.
5. **Access codes:** after the change, open Access Codes and confirm each link now uses `{NEW}`, not `mr7-4k.live` (regenerate/re-copy if needed).
6. **Old domain:** keep it pointed during the transition, or remove all references to it.

Quick check: every code link on the Access Codes page must show `{NEW}` and that domain must actually resolve.

Section B — Verify the API setup inside the panel

1. **Access code:** Access Codes ← a code of type **Reseller API**, status **Active**.
2. **IP list:** open the code ← **Restrictions** tab ← **Allowed IP Addresses** contains `158.220.81.202` (shown in the list box and saved with Add).
3. **Package groups:** the code's **Groups** tab has the sold package groups enabled, and each package has **Bouquets** assigned.
4. **Group permissions** (Edit Group ← Permissions): Can Use Reseller API ✓, Can Generate Mass Paid ✓, Can Delete Users ✓, User Delete Refund ✓.
5. **api_key:** from **Manage end-points / API Settings** — copy the key tied to the code. (The *Admin API Management* key is different and will not work.)

Section C — Verify from the server (live test)

Run from our server `158.220.81.202`. Replace `{NEW}`, `{PORT}`, `{KEY}`, then copy & paste.

1) Does the domain resolve?

```
getent hosts {NEW} || nslookup {NEW}
```

2) Does the endpoint respond? (safe, creates nothing) — action=user_info

```
curl -sS "http://{NEW}:{PORT}/msAPIufgk/reseller/index.php?api_key={KEY}&action=user_inf
```

Python fallback if curl is missing:

```
python3 -c "import urllib.request as u;print(u.urlopen('http://{NEW}:{PORT}/msAPIufgk/re
```

3) Read packages — action=packages

```
curl -sS "http://{NEW}:{PORT}/msAPIufgk/reseller/index.php?api_key={KEY}&action=packages
```

4) Dry-run create test (dry_run=1, no real creation)

```
curl -sS -X POST "http://{NEW}:{PORT}/msAPIufgk/reseller/index.php" -d "api_key={KEY}&ac
```

5) Local test on the panel host itself (bypasses DNS and IP whitelist)

```
curl -sS -H "Host: {NEW}" "http://127.0.0.1:{PORT}/msAPIufgk/reseller/index.php?api_key=
```

Try the other code `resellerapi` with the same commands if needed.

Section D — Interpreting the results

Response	Meaning	Action
<code>{"status":"STATUS_SUCCESS", ...}</code>	All good	Ready to connect
<code>IP FORBIDDEN</code>	IP not allowed	Add 158.220.81.202 to Restrictions
<code>api_key / authentication message</code>	Wrong key	Use the <code>api_key</code> from API Settings
<code>404 Not Found</code> (nginx)	Wrong domain/port or missing <code>server_name</code>	Do Section A
<code>could not resolve / Errno -3</code>	Domain does not resolve	Do Section A (A record)
Permission error on <code>create_line</code>	Missing permission	Enable Generate Mass Paid for the group

Section E — What to send us after success

Once you get a `STATUS_SUCCESS` response, send us:

1. The **full working URL** (final domain, port, and code).

2. The **api_key** tied to the code.
3. The **final approved domain and port**.

We will then connect the gateway in Reseller API mode directly.
